Implement Stack

Your script should contain three functions
1. push
2. pop
3. peep

User will be given choice to perform action from above three.

Script should be kept running until user chooses to exit.

Implement Queue

You script should contain three functions

1. enqueue
2. dequeue
3. peek

User will be given choice to perform action from above three.

Script should be kept running until user chooses to exit.

Implement Circular Queue You script should contain four functions 1. Front: Get the front item from queue. 2. Rear: Get the last item from queue. 3. enqueue(value) 4. dequeue() User will be given choice to perform action from above four. Script should be kept running until user chooses to exit.
Selection sort Use a static list Use selection sort to sort this list
Bubble sort Use a static list Use bubble sort to sort this list
Insertion sort Use a static list Use insertion sort to sort this list

Binary search Use a static list Use Binary search to find element asked by user Use one of the sorting algorithm that you have developed to sort list here
Matrix Multiplication 1. Take two 3x3 matrix. 2. take user inputs to fill it up. 3. Multiply them both and store it in another 3x3 matrix. 4. Display the result.
Find diterminent of 3x3 matrix
Pelindrom number

Randomly generate a 4-digit number. Ask the user to guess a 4-digit number. For every digit that the user guessed correctly in the correct place, they have a “cow”. For every digit the user guessed correctly in the wrong place is a “bull.” Every time the user makes a guess, tell them how many “cows” and “bulls” they have. Once the user guesses the correct number, the game is over. Keep track of the number of guesses the user makes throughout teh game and tell the user at the end.
 	
Say the number generated by the computer is 1038. An example interaction could look like this:
 	
Welcome to the Cows and Bulls Game!
Enter a number:
>>> 1234
2 cows, 0 bulls
>>> 1356
1 cow, 1 bull
...
Until the user guesses the number.

Create an ATM machine - User should be able get money out of it - User should be able to deposite money into it - You must ask card number and pin before any transaction - User can get overall information about his bank account - There should be a limit in one time transaction and total transaction in a day (Consider day as from starting of script to exit) - Limit on number of transaction - Let user choose the bank of ATM - Every ATM will have some initial balance - Every user has it's own bank - If user takes money from an ATM other than his bank take 5% cut in withdrawl amount Nice to have features: - Insert, update and delete users (Generate card number and PIN randomly) - Insert, update and delete ATMs - Insert, update and delete banks - Insert money into ATM (No database is needed for this it can be managed using dicts) Hint: You can manage all this with data dictionary data type.
Create a Tic Tac Toe game in python. 1. You should be able to play with two players. 2. You should be able to play against computer. After you complete simple game implement it in a way that computer never loses.
Find the factors of a number opimize it as much as you can
Find LCM and GCM of a number

Rearrange array such that A[A[i]] is set i for every element A[i]

Input:{1, 3, 4, 2, 0}
Output:{4, 0, 3, 1, 2}

Explanation:

A[0] = 1, A[1] becomes 0
A[1] = 3, A[3] becomes 1
A[2] = 4, A[4] becomes 2
A[3] = 2, A[2] becomes 3
A[4] = 0, A[0] becomes 4
